From Vision to Reality: A Formal Theory of Embodied Manifestation

Daniel Ray Edgar

July 25, 2026

Abstract

Every human-made reality exists twice: first as a representation in one or more minds, then as a physical arrangement produced through action. A building begins as a plan. A company begins as a model of a future institution. A changed life begins as an image of a person who does not yet fully exist. This paper develops a concise theory of that passage from vision to reality.

The central claim is that visualization can change the physical future when it changes attention, expectation, policy selection, and action. Biological state constrains which policies a person can reliably execute. Action changes the environment, and feedback updates both the person and the plan. I formalize this loop with a policy mixture model and prove three results within it. First, visualization requires a mediator: if policy and action do not change, an external outcome does not change under the ordinary causal graph. Second, an embodied state that enables more effective policies expands the set of reachable futures. Third, repeated well-directed attempts compound the probability of material success.

The theory integrates evidence from mental imagery, implementation intentions, placebo physiology, bioelectric signaling, sleep, circadian timing, metabolism, hydration, inflammation, habits, notifications, and contemplative practice. It also sets clear boundaries. Quantum effects occur in biology, but this does not establish voluntary selection of quantum timelines. DNA conducts charge, but this does not make ordinary language a genetic programming interface. U.S. Patent 6,506,148 and the Gateway memorandum are genuine primary records of proposed mechanisms and institutional inquiry, not conclusive experimental validation.

Alchemy, kundalini, theosis, Christ consciousness, and related traditions can be read as symbolic maps of disciplined transformation. The practical conclusion is strong without requiring magical causation: imagination supplies direction, the body supplies capacity, action supplies physical force, and feedback turns a private vision into a public reality.

1 The Claim

The phrase *manifest your reality* is used for several different claims. One is ordinary and true: a person imagines a future, organizes behavior around it, and helps bring it about. Another is possible but underspecified: vivid inner experience may change health, perception, and performance through mechanisms not yet fully mapped. A third is much stronger: thought alone selects an external quantum timeline or directly rearranges matter. These claims should not be treated as one.

This paper defends the first claim, studies the second, and turns the third into a testable boundary. The resulting view is neither trivial nor magical. Human beings are not passive observers of a fixed future. They are living causes inside the world. What they repeatedly represent changes what they notice, prepare for, attempt, build, and become. Those changes alter later physical states.

The simple causal chain is:

$$\text{vision} \longrightarrow \text{embodied state} \longrightarrow \text{policy} \longrightarrow \text{action} \longrightarrow \text{physical change} \longrightarrow \text{feedback}. \tag{1}$$

Each arrow matters. Vision without embodiment becomes fantasy. Capacity without direction becomes unused potential. Intention without policy remains a wish. Policy without action remains private. Action without feedback becomes repetition without learning. Manifestation is the complete loop.

This is also why the body matters. A sleep-deprived, inflamed, distracted, or chronically stressed person does not merely feel worse. That state changes attention, inhibition, learning, valuation, and the reliability of action. Conversely, recovery, practice, environmental design, and meaning can enlarge the range of policies that are available at the decisive moment. Biology is not destiny, but it shapes the menu from which agency chooses.

2 What Manifestation Means

The word *reality* needs a precise object. Three levels are sufficient.

Definition 2.1 (Mental plane)**.** The mental plane is the set of internal representations an agent can currently form: images, concepts, goals, counterfactuals, memories, and models of possible futures.

Definition 2.2 (Embodied plane)**.** The embodied plane is the agent's present capacity to perceive, regulate, decide, learn, and act. It includes attention, expectation, emotion, physiological state, skill, and action readiness.

Definition 2.3 (Physical plane)**.** The physical plane is the observable world in which actions have consequences: bodies, objects, documents, money, relationships, institutions, and environments.

The mental plane is not unreal. A representation is a physical process in a living nervous system and can be causally important before its object exists. Yet a mental model is not

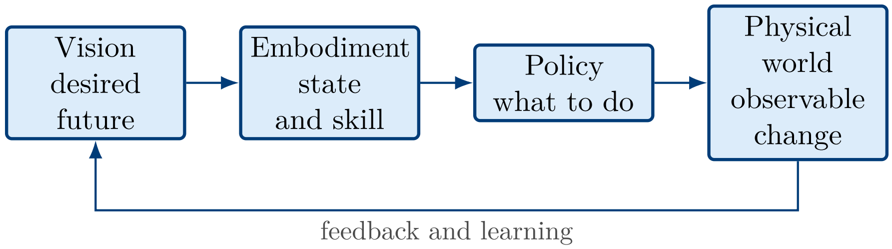

Figure 1: The passage from a private representation to a public result. Vision sets direction; embodiment determines capacity; policy organizes action; physical change returns evidence.

identical to the world it represents. The imagined house is not a house. It becomes one only when the representation controls drawings, budgets, contracts, tools, and coordinated labor.

This distinction gives a professional meaning to *astral visualization*. The term can describe a vivid symbolic experience in which a desired reality is perceived as already present. Such experience may carry unusual emotional force or a sense of self-transcendence [James, 1902, Yaden et al., 2017]. The paper does not require an astral substance. Its causal question is simpler: does the experience change the embodied policies that later change the world?

Manifestation, in the sense defended here, is therefore:

> *the process by which a represented future changes the policies of an embodied agent, whose actions increase the probability that the represented future becomes an observable state of the world.*

This definition preserves the power of the idea while making it measurable. It also prevents two errors. The first is fatalism: the future is not fixed because present action changes its distribution. The second is omnipotence: the agent acts inside material, social, and probabilistic constraints.

3 A Formal Model

Let V denote a visualized target, B the agent's biological and cognitive state, E the environment, π a policy or organized course of action, and Y a later physical outcome. The basic identity is:

$$P(Y \mid V, B, E) = \sum_{\pi \in \Pi(B,E)} P(Y \mid \mathrm{do}(\pi), B, E)\, P(\pi \mid V, B, E). \tag{2}$$

The first term inside the sum asks what happens if policy π is executed. The second asks how likely the agent is to select that policy given the vision, body, and environment. Visualization has power when it changes the weights assigned to useful policies. Biology and environment determine which policies are available and whether they can be executed reliably.

3.1 The mediation theorem

Theorem 3.1 (Mediation theorem)**.** *Assume the ordinary causal graph*

$$V \longrightarrow \pi \longrightarrow Y,$$

with B and E fixed. If

$$P(\pi \mid V = v_1, B, E) = P(\pi \mid V = v_2, B, E)$$

for every policy π, then

$$P(Y \mid V = v_1, B, E) = P(Y \mid V = v_2, B, E).$$

Proof. Apply Equation 2 to v_1 and v_2. The interventional outcome term $P(Y \mid \mathrm{do}(\pi), B, E)$ is the same in both sums because the policy, body, and environment are fixed. By assumption, the policy weight is also the same for every π. The sums are therefore equal. $\square$

The theorem says something practical and something scientific. Practically, an image that never changes attention, preparation, choice, or action should not be expected to change an external result. Scientifically, any reproducible effect on a shielded external system after every ordinary mediator is fixed would falsify this graph and require a new causal edge. The theorem does not declare such an edge impossible. It states what evidence would be needed.

3.2 The reachable-future theorem

For reliability threshold ρ, let $\Pi_\rho(B, E)$ be the set of policies the agent can execute with at least reliability ρ. For outcome threshold ϵ, define the reachable-future set:

$$\mathcal{A}_{\epsilon,\rho}(B, E) = \{y : \exists \pi \in \Pi_\rho(B, E) \text{ with } P(y \mid \mathrm{do}(\pi), B, E) \geq \epsilon\}\,. \tag{3}$$

Theorem 3.2 (Reachable-future theorem)**.** *Let B^+ and B^- be two embodied states in the same environment. If*

$$\Pi_\rho(B^-, E) \subseteq \Pi_\rho(B^+, E),$$

and every outcome reachable under B^- remains at least as likely under the same policy in B^+, then

$$\mathcal{A}_{\epsilon,\rho}(B^-, E) \subseteq \mathcal{A}_{\epsilon,\rho}(B^+, E).$$

If at least one additional policy in B^+ reaches an outcome not reachable in B^-, the inclusion is strict.

Proof. Take any $y \in \mathcal{A}_{\epsilon,\rho}(B^-, E)$. By definition, some $\pi \in \Pi_\rho(B^-, E)$ reaches y with probability at least ϵ. Set inclusion makes the same policy available in B^+, and the probability assumption preserves the threshold. Thus $y \in \mathcal{A}_{\epsilon,\rho}(B^+, E)$. If an additional policy reaches a new qualifying outcome, that outcome belongs only to the second set. $\square$

The result formalizes a familiar experience. When exhaustion removes the policy *have the difficult conversation calmly*, a relational future disappears from the reachable set for that moment. When training adds the policy *build and deploy the prototype*, futures that were once imaginary become reachable. Improved state does not guarantee an outcome. It changes the set of outcomes for which there is a credible path.

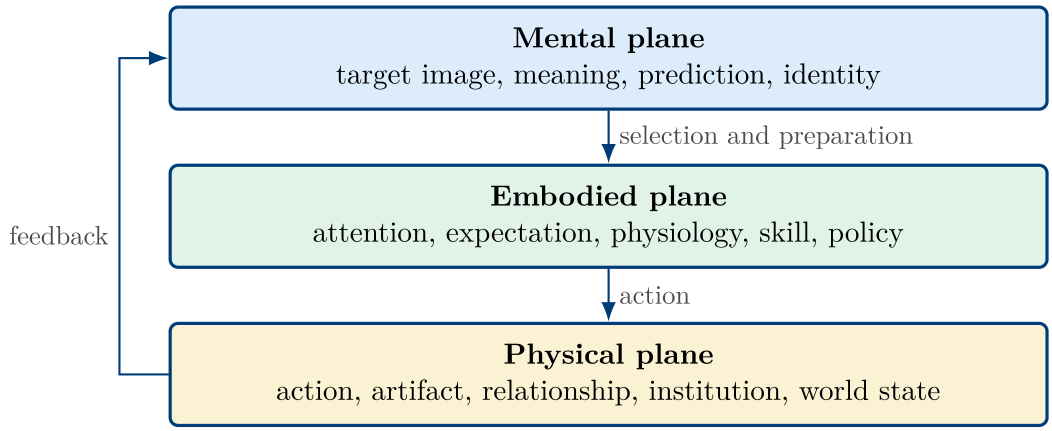

Figure 2: The three planes are not competing universes. They are stages in one causal process. A private model becomes physically consequential through an embodied agent.

3.3 The repetition theorem

Theorem 3.3 (Repetition theorem)**.** *Suppose an agent makes n conditionally independent attempts at a target, with success probabilities $p_1, \ldots, p_n$. The probability of at least one success is*

$$P(\textit{success by } n) = 1 - \prod_{t=1}^{n}(1 - p_t).$$

For any attempt with $0 < p_t < 1$, adding another attempt with positive probability or increasing any p_t strictly increases the cumulative probability.

Proof. The probability that every attempt fails is the product $\prod_{t=1}^{n}(1-p_t)$. The complementary event is at least one success. Adding a factor $1 - p_{n+1} < 1$ makes the failure product smaller. Increasing a p_t also makes its failure factor smaller. In either case the complement becomes larger. □

Real attempts are not perfectly independent, but the logic survives in richer models. A clear vision can increase the number of directed attempts, improve their quality, and make feedback useful. Small changes then accumulate. What looks retrospectively like a sudden manifestation is often the visible threshold of a long sequence.

4 How Vision Enters the Body

The formal model leaves an empirical question: how can a representation change policy weights? Four mechanisms are well supported.

Attention. A goal changes the relevance map through which the world is sampled. Once a target is represented clearly, cues related to it become easier to notice, encode, and retrieve. This is not the universe sending signs. It is selective perception serving an active model. Because no person can process every available signal, relevance is a genuine causal resource.

Rehearsal. Mental imagery recruits parts of the systems used in perception and action. In one study, kinesthetic imagery training changed brain signals and increased strength [Yao et al., 2013]. The careful inference is not that imagination replaces practice. It is that simulation can prepare the controller that practice uses. Effective visualization therefore includes process, obstacles, and response, not only the pleasure of completion.

Expectation. Expectations can alter internal physiology. Placebo research has connected expectation to dopamine release in Parkinson's disease and to measurable changes in pain-related brain activity [de la Fuente-Fernández et al., 2001, Wager et al., 2004]. These results do not show that belief can cure any disease. They do show that meaning is not outside biology. A representation can become a physiological input.

Implementation. A goal becomes much more executable when translated into an if-then rule: *if situation X occurs, I will perform action A*. Implementation-intention research shows why desire alone is weaker than a prepared policy [Sheeran et al., 2005]. Visualization supplies direction; implementation intentions supply grammar.

The same logic applies to identity. Repeatedly imagining oneself as a builder, athlete, parent, leader, or contemplative can influence which actions feel consistent with the self-model. That effect can be constructive or delusional. The difference is feedback. A useful identity produces observable evidence and updates when reality disagrees.

5 The Body Changes What Is Possible

The human body is not merely a vehicle carrying an independent mind. It is part of the decision system. Neurons signal electrically; cells maintain membrane potentials; tissues coordinate through chemical, mechanical, and bioelectric channels. Work on development and regeneration shows that bioelectric patterns participate in large-scale anatomical organization [Levin, 2021, Durant et al., 2019]. This is strong evidence for biological information processing. It is not, by itself, evidence that the body receives semantic commands from a cosmic field.

Several ordinary state variables change the reachable policy set.

Sleep and timing. Sleep deprivation impairs decisions that require updating from feedback [Whitney et al., 2015]. Circadian misalignment impairs performance in task-dependent ways [Chellappa et al., 2018]. A person may still hold the same dream while losing the ability to learn from the day's evidence. Rest is therefore not separate from manifestation. It protects the update step.

Energy, hydration, and inflammation. Metabolic state can alter decisions under risk [Symmonds et al., 2010]. Mild dehydration has been associated with changes in cognition and mood [Ganio et al., 2011, Armstrong et al., 2012]. Experimental immune activation can change neurobehavioral function [Grigoleit et al., 2011]. These findings do not mean every bad choice is caused by a biomarker. They show why state cannot be excluded from a theory of agency.

Food and the gut-brain axis. In a randomized inpatient trial, ultra-processed diets caused higher calorie intake and weight gain than minimally processed diets offered under matched conditions [Hall et al., 2019]. Microbiome interventions can affect reported emotional and neural measures, although results remain intervention-specific [Bagga et al., 2018]. Nutrition influences capacity through ordinary metabolic, endocrine, immune, and neural pathways. No quantum-field explanation is required.

Attention environments. Phone notifications impose measurable attentional costs even when the user does not respond [Stothart et al., 2015, Upshaw et al., 2022]. Habits are strongly coupled to stable contexts, and context change can disrupt them [Wood et al., 2005]. Recommendation systems are explicitly optimized to select what a user sees next [Covington et al., 2016]. Processed food and digital distraction do not prove a single conspiracy to suppress divinity. They do reveal incentive systems that profit when short-term consumption wins against long-term intention.

This is the grounded meaning of *frequency* and *coherence*. Frequency can refer literally to oscillation only when a rate is measured. In personal practice it is better used as a metaphor for a stable pattern of attention, emotion, physiology, and conduct. Coherence is alignment among goal, state, policy, and action. When those parts conflict, energy is spent without directed change. When they align, the same person becomes a more reliable cause.

6 Evidence and Boundaries

The paper uses four evidence levels. *Established* means replicated causal evidence or mature physical theory. *Supported* means convergent evidence with meaningful limits. *Plausible* means a testable extension. *Interpretive* means philosophical, phenomenological, or theological meaning rather than a laboratory result. Keeping these levels separate makes the synthesis stronger.

6.1 DNA, fields, and quantum language

DNA is genetic material, a regulated polymer, and a medium through which charge transport can occur [Crick, 1970, Virolainen et al., 2023, Zwang et al., 2018]. Calling it either a code *or* an antenna creates a false choice. It has several physical and informational properties. The specific claim that ordinary words semantically program DNA has not been established by blinded, independent, multilaboratory replication. Even literature sympathetic to a DNA "phantom effect" notes the replication problem [Gariaev et al., 2011, Brill, 2012].

The heart produces electrical and magnetic signals. Magnetocardiography measures fields in the picotesla range [Roth, 2024]. Measurement does not create a privileged three-foot boundary or demonstrate that the field broadcasts intentions into external reality. Similarly, action potentials involve voltage changes, but quoting one membrane voltage does not make the body a computer with a single global bit rate. Published estimates depend on what level is counted, and recent authors have disputed a proposed ten-bit-per-second behavioral figure [Kandel et al., 2021, Zheng and Meister, 2025, Sauerbrei and Pruszynski, 2025].

Quantum tunneling occurs in enzyme reactions, and quantum coherence has been studied in photosynthetic systems [Cha et al., 1989, Panitchayangkoon et al., 2010]. There is active disagreement about which forms of coherence biology actually uses [Duan et al., 2017]. Quantum-consciousness proposals exist [Hameroff and Penrose, 2014], while decoherence calculations show the scale problem faced by simple macroscopic accounts [Tegmark, 2000]. The many-worlds interpretation is an interpretation of quantum mechanics, not a demonstrated method for a person to choose a preferred branch [Vaidman, 2022].

6.2 What the patent and Gateway record show

U.S. Patent 6,506,148 B2, *Nervous System Manipulation by Electromagnetic Fields from Monitors*, describes a proposed method using pulsed monitor fields in the 0.1 to 15 Hz range [Loos, 2003]. Its specification relies substantially on subject-controlled tuning and subjective responses. A patent grant establishes that claims passed the applicable legal examination. The USPTO utility requirement is not a blinded clinical-efficacy standard [United States Patent and Trademark Office, 2026]. Separate neuroscience does show that visual systems can entrain to video displays under defined conditions [Williams et al., 2004]. That supports a narrower mechanism, not every claim in the patent.

The 1983 Department of the Army memorandum *Analysis and Assessment of Gateway Process*, later released under a CIA archive identifier, is a genuine government analysis of the Monroe Institute's Gateway framework [McDonnell, 1983]. It combines altered-state practice with Bentov, holographic, and quantum language. Its conclusion recommends further experiments and describes what might follow *if* the method works. The document is good evidence that the subject received serious institutional attention. Its own conditional language prevents it from being treated as a final report of successful validation.

The patent and memorandum are therefore valuable primary records. They show that claims about fields and altered consciousness entered formal technical channels. They do not replace controlled replication. The exact documents used here are archived with the paper so their wording and provenance remain auditable.

6.3 Compact claim audit

7 Ancient Maps of Transformation

Long before causal graphs, traditions described transformation with symbolic architectures. They need not be discarded because some modern anatomical claims are weak. They can be read at the level where they are strongest.

Alchemy. Hermetic and alchemical texts join an image of perfected matter with disciplined operations of separation, purification, and recombination [Copenhaver, 1992, Jung, 1968]. Psychologically, the pattern is clear: hold a form, expose the present self to a process, and embody the result. The gold is both a material aim and a symbol of integrated being.

Kundalini. Kundalini traditions provide maps of concentrated practice, ascending energy, and transformed consciousness [Bühnemann, 2011, White, 1996]. Contemporary reports describe powerful experiences and lasting effects, although the data are largely phenomeno-

Table 1: What the evidence supports and where it stops.

Claim	Status	Defensible conclusion
Cells use bioelectric signals	Established	Membrane voltage and bioelectric patterning participate in neural, developmental, and regenerative processes.
Imagery changes performance	Supported	Imagery can rehearse controllers and influence later performance; it does not replace physical execution.
If-then plans improve action	Supported	Implementation intentions convert goals into context-triggered policies.
Words directly program DNA	Unsupported	DNA responds to physical and biochemical conditions; semantic word effects lack independent replication.
The heart emits a field	Established	The field is measurable; a special consciousness radius or intention broadcast is not established.
Quantum effects occur in cells	Established	Specific molecular effects exist; quantum timeline selection by intention does not follow.
The patent proves manipulation	Documentary	It proves a method was claimed and granted, not that clinical efficacy was replicated.
Gateway proves astral travel	Documentary	It proves institutional analysis and proposed testing, not conclusive validation.
Kundalini describes real experience	Interpretive	The tradition and reported experiences are real objects of study; one universal physiology is not established.
Sacred secretion is monthly anatomy	Unsupported	Known cerebrospinal-fluid and pineal physiology do not establish the claimed cycle.

logical [Woollacott et al., 2021]. The disciplined claim is that practices can reorganize experience and identity. The stronger claim of one universal hidden anatomy remains open.

Theosis and Christ consciousness. Christian theosis concerns participation in divine life and transformation into likeness with God [Athanasius of Alexandria, 2011, Papanikolaou, 2020]. In the language of this paper, the highest image of the person becomes a regulative model for attention, conduct, sacrifice, and love. "Christ consciousness" is best treated as a modern interpretive label for this transformed orientation, not a laboratory measurement.

Sacred secretion. Claims of a universal monthly substance descending from the brain to the sacrum and returning to the head are not established by known cerebrospinal-fluid or pineal physiology [Hladky and Barrand, 2014, Nichols, 2018]. Mammalian brains can contain enzymatic machinery related to DMT biosynthesis, but this does not establish the popular cycle or its theological interpretation [Dean et al., 2019]. A practice can remain meaningful without a false anatomical proof.

Across these traditions, one structure repeats:

$$\text{image} \longrightarrow \text{discipline} \longrightarrow \text{transformed identity} \longrightarrow \text{transformed conduct.} \tag{4}$$

That structure is compatible with the formal model. The spiritual traditions speak in symbols about the selection and embodiment of a higher policy. Science can study the mediators without exhausting the meaning.

8 A Practical Materialization Protocol

The theory becomes useful only when it changes practice. The following protocol is a direct translation of the causal model.

1. Specify the physical target. State what will be observable if the vision becomes real. "Become successful" is not yet a target. "Publish the manuscript, place it in the portfolio, and obtain three qualified reviews" is. A physical criterion prevents feeling from being mistaken for completion.

2. Visualize the process and the identity. Represent the finished state vividly, then rehearse the process that creates it. Include the difficult email, the training session, the rejection, the recovery, and the next attempt. Imagine the kind of person who performs those actions reliably. Outcome imagery gives direction; process imagery prepares policy.

3. Convert vision into implementation intentions. Write if-then rules for the moments that matter: *if it is 7:00 a.m., I open the manuscript before messages*; *if I receive a rejection, I record the reason and send the next submission within twenty-four hours.* The rule moves choice from a future depleted state into a present reflective state.

4. Prepare the body. Protect sleep, circadian regularity, hydration, adequate nutrition, movement, and recovery. Seek clinical care when symptoms require it. This is not wellness decoration. It is maintenance of the system that must execute the policy.

5. Design the environment. Remove cues that trigger the competing identity. Disable unnecessary notifications, place tools where action begins, reduce friction for desired behavior, and add social commitments where they help. Willpower is one variable; environment changes the policy distribution before willpower is tested.

6. Act and produce evidence. Create a physical trace each cycle: a page, call, prototype, application, workout, conversation, or transfer of resources. Evidence tells the nervous system that the identity is no longer imaginary. It also exposes the plan to the world, where correction becomes possible.

7. Measure, learn, and repeat. Compare the result with the target. Keep the vision stable enough to guide action and flexible enough to learn. Update the policy, not merely the affirmation. Repetition then improves both the quality and number of attempts, which is the mechanism in the repetition theorem.

Contemplative practice can support several steps. Meditation has been associated with differences in default-mode activity, self-regulation, and, in some contexts, transcriptional measures [Brewer et al., 2011, Vago and Silbersweig, 2012, Black et al., 2013]. The responsible conclusion is not that meditation guarantees external outcomes. It can reduce automaticity, stabilize attention, and change the agent who meets the next choice.

The protocol is intentionally ordinary in its mechanics and extraordinary in its implication. A reality that does not yet exist can organize present matter through a living person. The future reaches backward as information in a model; the person carries that information forward as action.

9 Predictions and Conclusion

A theory earns credibility by risking failure. The following predictions separate the model from unfalsifiable affirmation.

Prediction 1. Process visualization combined with implementation intentions will outperform outcome visualization alone on externally scored goals. The advantage will be mediated by action frequency and execution quality.

Prediction 2. Restoring sleep and circadian regularity in disrupted participants will expand measured policy generation, feedback updating, and execution reliability on defined tasks.

Prediction 3. Notification removal and context redesign will improve intentional control most in participants whose baseline behavior is strongly cue-driven.

Prediction 4. Repeated directed attempts will explain apparent "sudden" manifestations better than outcome imagery alone when the action history is measured prospectively.

Prediction 5. Semantic DNA programming will fail blinded, multilaboratory testing unless a meaning-specific effect survives energy matching, translation, sham exposure, and open raw-data review.

Prediction 6. Longitudinal measurement will not reveal one universal monthly brain-to-sacrum-to-brain secretion cycle across healthy adults.

Prediction 7. Contemplative practice will change selected measures of attention, regulation, and self-transcendence through measurable mediators, but it will not reliably alter shielded random physical outcomes.

The final claim can now be stated simply. Human beings are powerful, but their power is not well described as omnipotent thought. It is the power to model what is absent, reorganize themselves around that model, and apply directed force to the world. The mind supplies a future before the future is physical. The body determines whether the future can be carried. Action gives the image public consequence. Feedback corrects the difference between desire and reality.

This is how the mental plane descends into the physical plane. Not by skipping causality, but by entering it. Not every dream will materialize, because other agents, chance, time, and material constraints are real. Yet no designed future arrives without first being represented. The image is not the finished world. It is the first causal form of that world.
